Variable Definitions

The following is a key to variables used in the output tables listed in this Appendix :

lnimr: natural log of the infant mortality (IMR) rate (deaths in first year of life per 1,000 live births)

lncmr: natural log of the child mortality (CMR) rate (deaths in first 5 years of life)

lnlifex: natural log of life expectancy at birth (e_0)

ad5pc: DAH spending per capita over previous five years

ad5pc_2: Square of **ad5pc**

lnad5pc: natural log of DAH spending per capita over previous five years

lnwt5pc: natural log of water aid per capita over previous five years

lnal5pc: natural log of all other aid over previous five years

lnigdp5: real GDP per capita over previous 5 year period

lnipop: natural log of recipient country population

ipolity2: Polity2 score

t5: time (in 5 year increments)

The following definitions apply in Donor Type Models

lnad15pc: natural log of DAH for donor type 1: Bi-laterals

lnad25pc: natural log of DAH for donor type 2: multilaterals

The following definitions apply in Sub-Sector Models

lnad15pc: natural log of DAH for sub-sector 1: Administration

lnad25pc: natural log of DAH for sub-sector 1: Training

lnad35pc: natural log of DAH for sub-sector 1: Infrastructure

lnad45pc: natural log of DAH for sub-sector 1: Basic Health Care

lnad55pc: natural log of DAH for sub-sector 1: Nutrition

lnad65pc: natural log of DAH for sub-sector 1: HIV/AIDS and other STDs

lnad75pc: natural log of DAH for sub-sector 1: Other Infectious Disease

lnad85pc: natural log of DAH for sub-sector 1: Family Planning

lnad95pc: natural log of DAH for sub-sector 1: Non-Specific

Note: lags of variables (in 5 year increments) are noted by
variablename_l

See text for additional information on variable definitions

Estimation Methods

As discussed in the text, the population mortality rate M_{it} follows a trajectory over time, where countries are indexed by i and time periods (in five year increments) by t . Other variables shift this trajectory up and down; these include the primary variable of interest, DAH_{it} and control variables, which include other forms of aid, GDP, population, and Polity2 (these are all components of the vector X_{it}). The mortality trajectory is then approximated by the following linear model:

$$M_{it} = \beta_0 + \beta_{1i}t + \beta_2DAH_{it} + X_{it}\beta_3 + \beta_4M_{it-1} + u_i + e_{it}$$

Other factors can also affect shift the mortality trajectory, as shown above. These include the lagged value of the dependent variable and an unobserved country effect, u_i , which varies across countries but is constant over time. This term captures the host of unobserved economic, political and cultural determinants of mortality and significantly reduces problems with omitted variable bias. The residual, e_{it} , is an independent error process. Finally, in most models the slope of the trajectory, β_{1i} , is assumed to be common across countries ($\beta_{1i} = \beta_1$). As specified above, however, it is possible to allow the slope to vary across countries (similar to the way that the u_i term allows for variation in intercepts).

The following models can be estimated as special cases of the general model above:

Static Models

1. *Bi-variate OLS* ($\beta_{1i} = \beta_1$, $\beta_3 = 0$, $\beta_4 = 0$, $u_i = 0$). This is a simple OLS regression model of mortality on DAH without any further controls.
2. *Multi-variate OLS* ($\beta_{1i} = \beta_1$, $\beta_4 = 0$, $u_i = 0$). This includes the complete set of explanatory variable including the time trend, but no lagged dependent variable.

Unobserved heterogeneity models

3. *First difference model* ($\beta_{1i} = \beta_1, \beta_4 = 0$). The dependent variable and each independent variable is differenced, meaning the previous value is subtracted from the current value (e.g., $x_{it} - x_{it-1}$). In this specification, the country effects, u_i , and the time trend t , are present in the model, but they are swept away by the differencing process.

4. *Random effects model* ($\beta_{1i} = \beta_1, \beta_4 = 0$). This model treats the unobserved country effects, u_i , as random draws from a normal distribution. It is estimated by maximum likelihood and is justified for large samples. Coefficient estimates, however, are biased if the unobserved effects are correlated with the explanatory variable, which will often be the case.

5. *Fixed effects model* ($\beta_{1i} = \beta_1, \beta_4 = 0$). This model treats the country effects as fixed parameters which can be estimated by OLS after subtracting the country-specific mean for each variable. It is equivalent to including a dummy variable for each country. Probably the most attractive feature of this model is that correlation between u_i and other explanatory variables does not cause bias.

Dynamic Models

6. *Lagged dependent variable model* ($\beta_{1i} = \beta_1, u_i = 0$). This model has no fixed effect and a common time trend. However, the inclusion of the lagged dependent variable often has similar consequences to including fixed effects since both approaches involve shifting the time trajectory based on country-specific unobservables.

7. *Dynamic panel model* ($\beta_{1i} = \beta_1$). This model captures the full dynamic specification above except that the slope is assumed constant. As Nickel (1981) showed, however, estimates of

parameters are biased. However, Monte Carlo simulations by Judson and Owen (1999) suggest the bias is mostly a problem with respect to β_4 , a parameter of little interest here.

The dynamic panel model will be estimated two ways. The first approach is to use the simple fixed effects model with OLS, which will be done here. Second, GMM estimation using the common Arellano-Bond (1991) estimator is feasible. The Arellano-Bond approach takes first differences of the data and then uses lagged values of the variables as instrumental variables. This is a highly effective way to account for the obvious endogeneity of many of the variables in the model, including DAH, but the usual cost of instrumental variable regression, including GMM, is much higher standard errors. The Arellano-Bond estimates are consistent, but are designed for large-N studies. The small-sample properties of these estimators are not well known. Thus we have a tradeoff of a reduction in endogeneity bias at the cost of precision. The Arellano-Bond estimator also treats slope coefficients as fixed, as do the previous models.

8. *Latent Growth Model ($\beta_4 = 0$)*. This last model is part of a class of models that go by many names including random coefficient models, mixed models, hierarchical linear models and multi-level models. Its strength is the highly flexible functional form that allows both random intercepts and random slopes. Furthermore, in the estimation results to follow, arbitrary correlation between the random effects in the model is allowed (and proves to be important). Latent growth models, however, also rely on large sample properties of maximum likelihood estimation for their justification and are not necessarily unbiased in small samples. They also include no lagged dependent model.

MAIN ESTIMATES: DAH Effectiveness (Infant Mortality)

Notes:

DAH spending (lnad5pc) reported in Table 1 for all models
Models 2, 6, 7a, 7b are reported in Table 2.
